Retractable protective structure (ROPS)

E2010EN3, May 2002
The protective structure should only be in its retracted position in connection with transportation by lorry, train, ship, etc. The protective structure can be retracted either forward or backward. When retracting it forward, protect the steering wheel and the cover of the instrument panel from damage by chafing. The structure should preferably be retracted backwards (see figure 2) to give the machine and the structure the best protection against damage.

Risk of being crushed when raising and lowering the exhaust pipe.

To retract the protective structure, unscrew the securing screw (1), pull out the cotter pin (2) and pull out the bolt (3). Do this on both sides of the structure. If there is sufficient space the structure should preferably be retracted to the rear.

Restore the cotter pins and the bolts into position after retracting the structure.

Proceed in the reverse order to the above when raising the structure.

Always ensure that the structure is locked in its raised position before driving the roller.

Lubricate the securing screw (1) and the bolt (3) occasionally with waterproof grease.

If the roller is equipped with a retractable protective structure (ROPS), then the machine may only be operated with the structure raised and locked in position.
